A RECLASSIFICATION OF THE
NORTHERN SHAPLEY-AMES
GALAXIES

SIDNEY VAN DEN BERGH

1960
TORONTO, CANADA

A RECLASSIFICATION OF THE NORTHERN SHAPLEY-AMES GALAXIES

INTRODUCTION

The Shapley-Ames catalogue of galaxies brighter than the thirteenth magnitude, which was published almost thirty years ago, is still the only complete survey of bright extra-galactic nebulae, which covers the entire sky. The nebular types given in the Shapley-Ames (1932) catalogue were derived from thirteen different sources and are both inhomogeneous and incomplete. The recent publication of the Palomar Sky Survey has made it possible to reclassify all the northern Shapley-Ames galaxies on a homogeneous system. 935 of the 1,249 galaxies contained in the Shapley-Ames catalogue are located in the region north of $\delta = -27^\circ$, which is covered by the Palomar Sky Survey.

THE CATALOGUE

The first three columns contain the name of each galaxy and its 1950 co-ordinates, taken from the Shapley-Ames catalogue. For convenience the entries have been arranged in order of increasing NGC or IC number, rather than by right ascension for 1950.

The fourth column contains the DDO type and luminosity class. The classification system for galaxies of types Sb, Sc, Ir, SD and N has been described elsewhere (van den Bergh 1960a, 1960b).

A short description of types E, Sa and SBa is given below:

E—Unresolved galaxies with elliptical isophotes. Surface brightness decreases smoothly with increasing distance from the nucleus. E and S0 galaxies cannot be distinguished on the Sky Survey prints. Highly flattened objects of type S0 have therefore been denoted by the symbols E8 and E9.

Sa—Unresolved galaxies with more or less elliptical isophotes. Surface brightness decreases more abruptly at edge of disk than in type E.

SBa—Smooth unresolved main body and bar. In some cases surrounded by unresolved halo or ring segments.

The spectral types in column 5 were taken from Humason *et al.* (1956). The Yerkes concentration class Y in column 6 was taken from Morgan (1958). The integrated colours C_0 in column 7 were taken

from Holmberg (1958) and corrected for galactic absorption by the equation

$$C_0 = C - 0.06 \operatorname{cosec} |b^I| \quad (1)$$

The diameters in column 8 were measured on the blue prints of the Palomar Sky Survey. For galaxies of types Sa, Sb, Sc and Ir the diameters are maximum diameters. On the whole these diameters agree rather well with those given in the Shapley-Ames catalogue. From those galaxies with diameters $\varphi \geq 1.0$ minutes of arc one obtains

$$\text{Sb I, I-II, II} \quad \tilde{\varphi}_{\text{SA}} = 1.00 \tilde{\varphi}_{\text{DDO}} \quad (2)$$

$$\text{Sc I, I-II, II} \quad \tilde{\varphi}_{\text{SA}} = 0.98 \tilde{\varphi}_{\text{DDO}} \quad (3)$$

$$\text{Sc II-III, III, III-IV} \quad \tilde{\varphi}_{\text{SA}} = 1.07 \tilde{\varphi}_{\text{DDO}} \quad (4)$$

$$\text{S IV, IV-V, V} \quad \tilde{\varphi}_{\text{SA}} = 1.06 \tilde{\varphi}_{\text{DDO}} \quad (5)$$

The smooth radial decrease of the surface brightness in elliptical galaxies makes it impossible to determine maximum diameters with confidence. The diameters which are given in the catalogue might be described as "diameters of maximum contrast" on the Sky Survey prints. It should be emphasized that these diameters are quite uncertain. For elliptical galaxies the relation between the Shapley-Ames and DDO diameters is given by

$$\text{E} \quad \tilde{\varphi}_{\text{SA}} = 1.36 \tilde{\varphi}_{\text{DDO}} \quad (6)$$

The apparent integrated magnitudes of galaxies were taken from the following sources and are listed in order of preference:

1. Holmberg (1958).
2. Stebbins and Whitford (1952).
3. Humason *et al.* (1956).
4. Pettit (1954).
5. Shapley and Ames (1932).

The Pettit and the Stebbins and Whitford magnitudes were not used in those cases in which the maximum diameter of the galaxy greatly exceeded the size of the diaphragm used in their photoelectric observations. Only magnitudes by Holmberg are given in two decimals.

Column 10 gives the distance moduli of those galaxies to which luminosity classes could be assigned. The magnitude calibration was

taken from Table I. The apparent distance moduli were corrected for galactic absorption by the equation

$$(m-M)_0 = (m-M) - 0.24 \operatorname{cosec} |b^r| \quad (7)$$

Those distance moduli in column 11 which are given to one decimal were derived from the observed radial velocities of individual field

TABLE I
MAGNITUDE CALIBRATION OF LUMINOSITY CLASSES

Type and Class	\bar{M}_{pg}	Type and Class	\bar{M}_{pg}
Sb I	-20.4	Sc I	-20.0
Sb I-II	-19.9	Sc I-II	-19.7
Sb II	-19.4	Sc and Ir II	-19.4
Sb II-III	-18.6	Sc and Ir II-III	-18.9
Sb III	-18.0	Sc and Ir III	-18.3
		Sc and Ir III-IV	-18.0:
		S and Ir IV	-17.3:
		S and Ir IV-V	-16.1:

galaxies. Those given to two decimals were obtained from the mean redshifts of cluster members. A Hubble constant of 100 km./sec./mpc. was assumed.

The number of individual distance moduli obtained by different methods are given below:

From DDO luminosity classifications.....	411
From radial velocities of field nebulae.....	365
From cluster moduli.....	244

An asterisk in the last column refers to a note at the end of the table.

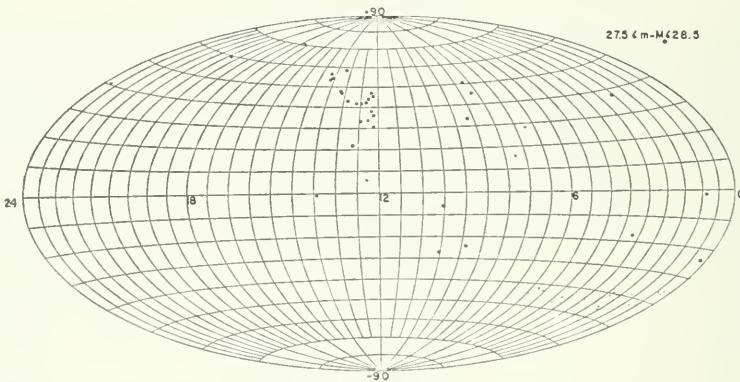

THE SPACE DISTRIBUTION OF GALAXIES

The catalogue contains distance moduli for 82 per cent. of the northern Shapley-Ames galaxies. The data are therefore sufficiently complete to investigate the spatial distribution of the nearer galaxies:

$$26.5 \leq m-M_0 \leq 27.5$$

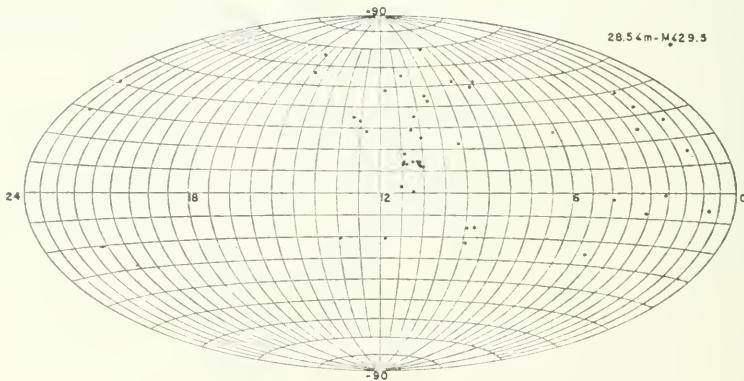

Eight of the ten Shapley-Ames galaxies within this distance interval are members of the M81 group.

$$27.5 \leq m-M_0 \leq 28.5 \text{ (Figure 1)}$$

Most of the galaxies in this distance interval are members of the Canes Venatici cluster. No other clusters are apparent in the figure.

$$28.5 \leq m-M_0 \leq 29.5 \text{ (Figure 2)}$$

Only two small clusters show on the figure. They are the M96 group ($\alpha \simeq 10^{\text{h}}40^{\text{m}}$, $\delta \simeq +13^\circ$) with $\bar{V}_e = +676$ km./sec. and the M66 group ($\alpha \simeq 11^{\text{h}}10^{\text{m}}$, $\delta \simeq +14^\circ$) with $\bar{V}_e = +598$ km./sec. The small difference in radial velocity and the small angular separation of these two groups suggests that they are physically associated.

REMARKS

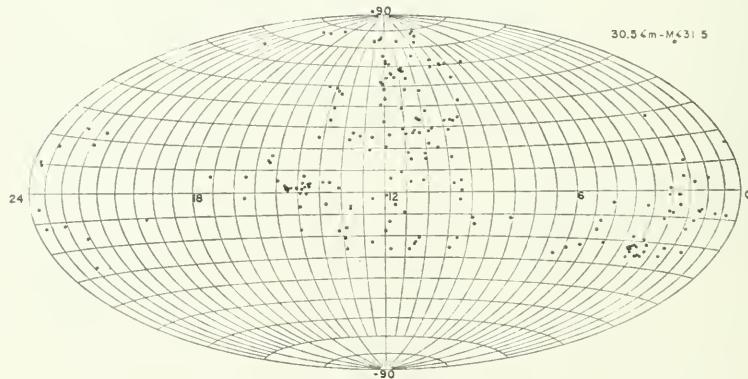

- NGC 178 Late type, has one resolved arm.
NGC 275 Interacting with NGC 274.
NGC 474 Fuzzy nucleus surrounded by segments of nebulous ring. Interacting with NGC 470.
NGC 520 Colliding galaxies?
NGC 1068 Seyfert galaxy. Halo.
NGC 1415 Diameter does not include faint "tidal arms".
NGC 2149 Probably galactic reflection nebula.
NGC 2207 Interacting pair.
NGC 2782 Seyfert galaxy.
NGC 2835 Spiral arms of low surface brightness.
NGC 2993 Interacting with NGC 2992.
NGC 3077 Seyfert galaxy.
NGC 3227 Seyfert galaxy.
NGC 3368 This galaxy (M96) is a member of a small class of objects with a bright main body with tightly coiled spiral arms surrounded by a faint halo. Other members of this class are NGC 1068 (M77) and NGC 4736 (M94).
NGC 3516 Seyfert galaxy.
NGC 3690 Two colliding galaxies.
NGC 4038 Colliding with NGC 4039.
NGC 4051 Seyfert galaxy.
NGC 4151 Seyfert galaxy.
NGC 4258 Seyfert galaxy.
NGC 4342 Identification uncertain.
NGC 4568 Interacting with NGC 4567.
NGC 4647 Interacting with NGC 4649.
NGC 4736 M94, has halo similar to those of M77 and M96.
NGC 4826 M64 is a very peculiar object. A blue plate taken with the 74-in. telescope shows tightly wound rather fuzzy spiral arms on which a large obscuring cloud is superimposed. The declination given in H.A. 88 should be increased by 10'.
NGC 4889 In Coma cluster. Misidentified as NGC 4872 in H.A. 88.
NGC 4902 Both radial velocity and luminosity classification place this galaxy beyond the Virgo Cluster.
NGC 4941 The structural peculiarities of this galaxy are similar to, but less pronounced, than those in the Seyfert galaxy NGC 4151.
NGC 5377 Appearance similar to that of NGC 4941 and the Seyfert galaxy NGC 4151.
NGC 5548 Seyfert galaxy.
NGC 6814 Seyfert galaxy.
NGC 7469 Seyfert galaxy.
Anon 1 Has S V companion at $\alpha(1855) = 0^{\text{h}}54^{\text{m}}$, $\delta(1855) = -8^{\circ} 25'$.

$29.5 \leq m-M_0 \leq 30.5$ (Figure 3)

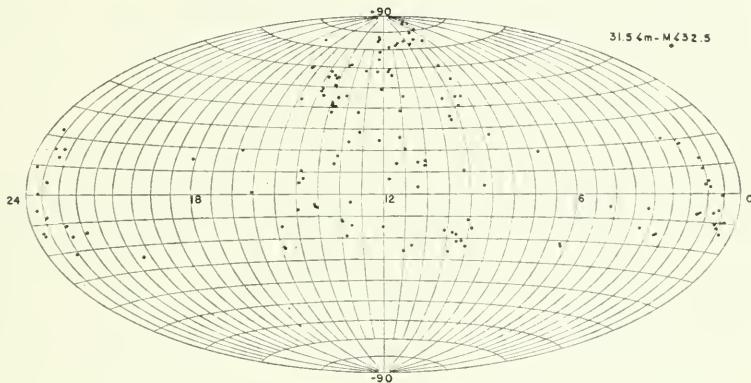

In this distance interval the Virgo cluster is the most prominent feature. Early type galaxies predominate in the nucleus of the cluster at $\alpha \simeq 12^{\text{h}} 25^{\text{m}}$, $\delta \simeq +13^{\circ}$. A secondary clustering of predominately late type galaxies is located at $\alpha \simeq 12^{\text{h}} 20^{\text{m}}$, $\delta \simeq +5^{\circ}$. The figure shows the southern extension of the Virgo cluster as a loose grouping of galaxies near $\alpha \simeq 12^{\text{h}} 50^{\text{m}}$, $\delta \simeq -10^{\circ}$. The Ursa Major cluster ($\alpha \simeq 12^{\text{h}} 00^{\text{m}}$, $\delta \simeq +50^{\circ}$) and the NGC 4274 group ($\alpha \simeq 12^{\text{h}} 15^{\text{m}}$, $\delta \simeq +30^{\circ}$) also show on the figure. The NGC 4274 group is probably somewhat closer to us than the Virgo Cluster. The NGC 3193 group. ($\alpha \simeq 10^{\text{h}} 10^{\text{m}}$, $\delta \simeq +23^{\circ}$) is possibly associated with the Virgo cluster complex.

$30.5 \leq m-M_0 \leq 31.5$ (Figure 4)

The figure shows a concentration of galaxies near $\alpha \simeq 14^{\text{h}}40^{\text{m}}$, $\delta \simeq +2^{\circ}$, which are apparently associated with the NGC 5850 group. The figure also shows a loose clustering of galaxies near $\alpha \simeq 3^{\text{h}}25^{\text{m}}$, $\delta \simeq -23^{\circ}$.

$$31.5 \leq m-M_0 \leq 32.5 \text{ (Figure 5)}$$

No conspicuous clustering is apparent in this distance interval.

THE LUMINOSITY FUNCTION OF GALAXIES

The frequency with which different DDO classification types occur among all Shapley-Ames galaxies north of $\delta = -27^{\circ}$ is given in Table II.

TABLE II
FREQUENCY OF CLASSIFICATION TYPES
Determined from the classification of 935 Shapley-Ames Galaxies

Type	Frequency
E (including S0)	22.9 per cent.
Sa	7.7
Sb	27.5
Sc (including S IV and S V)	27.3
I _r	2.1
Other	12.5

Luminosity classes could be assigned to about 80 per cent. of all galaxies of types Sb, Sc and Ir.

The number of Shapley-Ames galaxies of different types and luminosity classes is given in Table III.

TABLE III
OBSERVED FREQUENCY OF SHAPLEY-AMES GALAXIES

Type	Sb	Sc	Ir
Class			
I	37.5	30.5	0
I-II	22	14	0
II	58	68	1
II-III	37	22	0
III	36	31.5	3.5
III-IV	0.5	9.5	2
IV		21	6
IV-V		8.5	4.5
V		1	0

Using the magnitude calibration of Table I the observed frequency distribution of galaxies over the luminosity classes may be converted to relative space densities, if one makes the following assumptions: 1. The distribution of galaxies throughout space is uniform. 2. The degree of completeness of the Shapley-Ames catalogue depends on apparent magnitude only, i.e. the Shapley-Ames catalogue does not discriminate against galaxies of a particular type or luminosity class.

The assumption of a uniform space distribution of galaxies is probably valid for galaxies of luminosity classes I to IV. However, for fainter objects the Shapley-Ames catalogue contains only galaxies in the immediate vicinity of the local group. The space density of galaxies in the vicinity of the local group is probably higher than average. The assumption of a uniform distribution of galaxies will therefore lead to an overestimate of the space density of objects of luminosity classes IV-V and V. This effect is compensated for to some extent by the fact that the Shapley-Ames catalogue is more incomplete for large galaxies of low surface brightness than for small galaxies of high surface brightness. The faint end of the computed luminosity function must however be regarded as quite uncertain.

TABLE IV
RELATIVE SPACE DENSITY OF GALAXIES

Luminosity Classes	Approximate magnitude limits	Sb	Sc	Ir	Total
I, I-II	-20.5 to -19.5	0.9	1.0	0	1.9
II, II-III	-19.5 to -18.5	7.5	4.9	0.04	12.4
III, III-IV	-18.5 to -17.5	11	10	1.3	22.3
IV	-17.5 to -16.5	0	17	4.8	21.8
IV-V	-16.5 to -15.5	0	36:	19:	55:

Table IV gives the relative space densities for galaxies of different types and luminosity classes. The data have been normalized in such a way that they refer to a volume which contains one supergiant galaxy of type Sc. The table shows that the luminosity function of galaxies increases rapidly as one goes to fainter absolute magnitudes. The results for Sc and Ir galaxies are in fair agreement with those obtained by van den Bergh (1960a).

It is of some interest to note that the ratio of the number of spiral galaxies to the number of irregular galaxies increases rapidly as one goes to intrinsically brighter galaxies.
